This is the analysis output companion supplement to “Initial quantitative development of the Norse Feedback system: A novel adaptive multidimensional tool for use in routine mental healthcare.” **If you are NOT reading this in the HTML version, we strongly advise that you do so, as this document is too long to navigate as a PDF.** Proceed to this webpage (https://osf.io/6xvmf/?view_only=fcbfbb26e65c4c7bbb6e8cede3e975bc), download the HTML version, and open that file using your web browser. The contents are identical to this document.

Summary

This supplement is ordered roughly by the order of the manuscript.

The *Preliminary* section covers some essential but not substantively important work. Specifically it includes the R language code for the custom functions used in these analyses, to ease replication.

In *Study 2: Scale performance*, we present information on each scale’s reliability (Cronbach’s alpha, mean item-total correlation, and alpha if removed statistics), unidimensionality (scree plot, eigenvalue ratio, actual eigenvalues, and factor analysis output including goodness of fit), a graded response model for that scale, along with DIF analyses for gender and sample (clinical vs. nonclinical). The outputs are a combination of standard software-generated outputs and synthesized results.

These analytic outputs are already described in the text, but as we could not feasibly include all meaningful information for each scale in a single table, interested readers are directed to these individual scale analyses. Relevant DIF output includes the number of items flagged for DIF, along with the magnitude of effect size.

In *Study 2: ROC curves*, we present visual representations of the scales’ discrimination abilities between the clinical and nonclinical samples in this study.

In *Study 3: Scale performance*, we present very similar analyses to those presented in *Study 2: Scale performance*. The primary differences are in the group comparisons for DIF analysis. Outputs are similar or exactly the same.

The *Session Information* section contains the custom functions and loaded packages required to run these analyses.

Preliminary

Loaded libraries are found at the end of this document, along with version numbers of packages and R. We omit the call here for legibility.

Functions

Several convenience and analysis functions are defined at this point in the report with suppressed output, and are repeated in the *Session Information* section at the end of the document.

These functions rely on objects of type `grm` from the package `{ltm}` and type `roc` from the package `{pROC}`, among others. Again, they are actually defined at this point in the analysis code, but are not presented until the final section of this document for reference.

All installed packages are included in the Session Information section below. The subsequent code loops through different repeatable reports, each with several functions for each scale, and knits a single report from them.

Reading data

This section imports data from external repositories, the location of which is obscured for security reasons. Some (but not all) analysis objects are read into the global environment from previously-saved locations. This reduces compilation time of this supplement. Reproduction of analyses is still demonstrated within the code below. Interested readers may examine all code upon request (to AAM), though most analysis code is not included for here for clarity.

Study 2: ROC curves

For each scale, unadjusted scale scores are compared between the clinical and nonclinical samples in Study 2. For those scales that demonstrated substantial sample-based DIF (Connectedness, Demoralization, Pressure from Negative Affect, Relational Distress, and Somatic Anxiety), these comparisons should not be interpreted.

In all cases, the ROC curve and the area under the curve are presented below. The AUC appears in the manuscript as well.

Attachment

```
## Area under the curve: 0.6532
